

Week 11: Implementing AI in Organisations

Video 1: Module Overview

Today, we're going to talk about what it means to implement AI in organisations, and imagine a world where AI isn't just a buzzword, but it's a powerful tool driving real business results. However, the path to AI success is littered with pitfalls, and we've all heard stories of very promising AI pilots that get stuck in what I call a purgatory, never reaching their full potential. Today, in this module, we will dive beyond the hype. We'll equip you with the knowledge and the tools that you need to navigate the AI landscape effectively. We'll explore how to align AI initiatives with your business strategy, build high performing teams and most importantly how to avoid the pitfalls of the pilot purgatory. But AI isn't just a set it and forget it solution. We'll also have to delve into the importance of continuous evaluation and adaptation ensuring that your AI models deliver long-term value. Join me as we explore the practical steps to turn AI from a buzzword into a sustainable competitive advantage for your organisation. Today, I want to focus on two main outcomes. One, to help you understand the strategic, the tactical and the human aspects of successfully integrating AI into your organisation. And secondly, I hope to be able to equip you with enough knowledge, so you can prepare a road map to implement AI in a way that supports your workforce and aligns with your organisation's values and ethics.

Video 2: Implementation Framework - Strategy

So, let's start by talking a little bit about how AI aligns to the business strategy. In today's dynamic business landscape, staying ahead of the curve requires embracing technological advancements. Artificial intelligence is rapidly transforming industries. It's offering unparalleled opportunities for efficiency, for innovation and for growth. But simply deploying solutions isn't enough, it has to be aligned with your company's goals. These powerful tools, in fact, otherwise can become very expensive distractions. Just imagine if you invest heavily in an AI-powered customer service chatbot only to discover later that it doesn't address a core customer pain point or it doesn't align with your vision for personalised customer experiences. What a waste of expensive resources and time it would be. So, the point I'm trying to make is that AI is actually capable of very, very significant transformation. But it's important to make sure that you are clear about your business strategy and the business goals before you embark on an AI strategy. Without this alignment between the business strategy and the AI strategy, your initiatives can get siloed. They can potentially get misdirected, and it could lead to suboptimal outcomes, and as I said earlier, wasted resources. To help you think through how you do this, I'm going to give you this checklist. It's a nine step checklist and it starts by helping you, first of all, understand what your business goals are. Now your goals can be related to customer satisfaction, improving efficiency and reducing cost, or it could be just around innovation. Whatever it be, it's quite important to make sure that you're clear about the goals that you're trying to meet and then focus on that single-mindedly. The next step, obviously, is to identify the use cases after a comprehensive assignment.

So, what's important here is to look at your use cases based on your business goals and then prioritise them based on the value that they could potentially add and two, potentially, the ease for implementation. The third step is to set up teams. Now look, to usually to implement any AI, you will need representation from different functions. So, operations, marketing, customer service, potentially, finance. You'll need to be able to set up these teams and then charter them to start solving that use case. The other thing is to be able to establish KPIs because it's quite important to establish very early what are the outcomes that you're looking for. Establish KPIs that measure these outcomes quite directly. Then you come to the data quality and governance issue, which is all around establishing robust governance practices, ensuring data integrity, security, and compliance, especially with many of these new regulations like GDPR and CCPA and so on. Then, you come to the stage of having actually built a model. You need to prototype it. So, prototyping is, as we have all talked about, is basically, shall I say, simulation of the reality. It's a model of what the reality looks like. Talent is everything. You and me know that. And so therefore, it's extremely important to invest in talent and training. The other aspect of AI, of course, is the unintended consequences. And therefore, it's quite important to embrace ethical and responsible AI to be prepared for what they call explainable AI, which is, and I'll explain to you that in a minute, but it's really being able to convince the user about the transparency behind the model that has been built. And finally, in order to be able to implement, you got to measure and communicate the impact. Let's talk a little bit about what explainable AI means. Explainable AI is essentially the discipline that offers a clear explanation of your decisions and your actions. They aim to make AI decision-making transparent. They allow users to understand how conclusions are reached, and most importantly, it is all about fostering trust and accountability. So, what are the benefits of explainable AI? The most important benefit of explainable AI is that it offers insights into the AI process. And this is especially crucial in industries where it is quite important to understand the decision part. So, for example, in finance or in healthcare. The second benefit of explainable AI is that this helps to engender trust and greater the trust increased is the adoption. And then finally, and I think this is extremely important in today's context, explainable AI also helps to manage for regulatory compliance. There are many challenges in the path of explainable AI. One is the sheer complexity of these models. Many of them involve deep learning models which go through several layers of the tree structure and sometimes it becomes fairly difficult to explain this entire logic. The other important challenge is the performance trade-offs and the performance trade-offs are usually because you're trying to enhance the explainability on the one hand and without really in a significant way impacting the performance of the model itself. The other challenge, of course, is to be able to keep biases out, the human bias which usually creeps in the selection of the data in itself. But I think these are important challenges to contend with. These are important considerations to deal with and overall, the importance of explainable AI and the benefits of explainable AI far outweigh the challenges and considerations.

There are many frameworks that are available out there in terms of how to implement AI. The one that I would recommend for you to have a look at is McKinsey's model. McKinsey's model is a comprehensive framework and it identifies five key areas. The first, it says is identify the use cases. We talked about

this a little earlier. And identification of the use case in turn is directly a function of being clear about the outcomes or the problem that you're trying to solve. And therefore, the first step is to be able to clearly say that these are the problems I need to solve. The second step is to be able to identify the data that is required. The data may not reside in one single source. So, be able to build that ecosystem and be able to source data from different parts of the organisation is the second challenge. The third is identifying the tools and the techniques that are required. You may not have all of them. You need may need to take a build or buy decision. You may need to also decide on what is your approach towards failure. And so these are important steps in deciding how to move forward. The next and the most important step in my view is the integration of the workflow, which is how do you integrate AI into the workplace processes. This usually happens after your prototypes are done and after the model has been proven. And this is the stage at which you are trying to scale the AI model that has been created. And finally, I would say an extremely important part of successfully implementing AI is to be able to adopt a culture, a culture of openness, a culture of collaboration, a culture of trust, so that any bias or any other unintended consequences of the AI model are quickly surfaced before it becomes too late.

Video 3: Case Study: Apollo and Its Journey of Digital Transformation

Let's talk about the case study on Apollo and its journey of digital transformation. I'm assuming all of you have had a chance to read the case, and I wanted to pose these three questions to all of you. The setting of the case is 2019-2021, that is just over the COVID period. Apollo Hospitals, Chennai, has embarked on a major digital transformation journey, and this, one of the senior executives at Apollo Hospitals is quoted as saying. He's doing this for greater asset utilisation and optimisation of peak loads, which is a critical challenge. He also says the consumer will always be at the centre of the health model rather than the institution. What does that say about Apollo's digital transformation intent and outcomes?

Let's examine that carefully. If you think about it, I think Apollo was trying to improve efficiency and to reduce cost. They were also trying to become far more data-driven in their decision-making. And finally, as Mr. Shiva Kumar says, they wanted to place the patient at the centre of the entire model as opposed to placing the hospital, the institution, at the centre of it. So, that entailed a very different mindset, a very different approach, and a very different process to problem solving. What were some of the outcomes that they were looking for? Service efficiency. Obviously, they were also looking through better customer experience to improve their brand strength because they wanted to make sure that they would definitely tap into those patients who had a higher willingness to pay. The other dimension to this was the consultants of the physician's experience and the clinical excellence at the organisation, at the hospital itself. So, you can see that the outcomes that they wanted was, on the one hand, improved customer experience, patient, in this case, patient experience through better service efficiency and improving their brand strength. But on the other hand, they also wanted to improve the experience of the consultant or the physician. What were some of the components of this transformation program? One, of course, looking at their entire operating model and figuring out how to transform the operating model, which included looking at their organisation structure, their roles, the jobs, as well as some of

the skills that are needed. It also required them to look at their leadership and how they transform their own leadership. And finally, they needed to look at the information flows between the different parts of the hospital. To analyse this case, I'd like you to consider this framework, which was developed first by a gentleman called David Rogers, and you can, if you want to know more about this, you can certainly look at his book, The Digital Transformation Playbook. He presents this model, which is also commonly known as the CCDIV model, customers, competition, data, innovation, and value. I believe it's a very neat way of capturing what it requires to implement digital transformation. Let's spend a minute looking at each one of these components. What does customers mean? Customers in this case refers to the network of customers because, as you know, there is the concept of network effects of customers talking to each other, and so in a digital transformation you are trying to harness the power of these information networks or customer networks. Competition. The whole objective of a digital transformation program is to differentiate yourself from competition. And one of the ways many organisations have started doing it is to move towards what they call platforms. And so creating a platform structure where, from a customer experience standpoint or a patient experience standpoint, you bring together all the providers who are intrinsic and essential to providing the end-to-end journey for the patient. Data. In this case, data means using data to create assets. How do you use your data to create information, knowledge, and eventually wisdom which can be monetised and sold to the patients or their caretakers? Innovation. Innovation refers to the whole cultural aspect of rapid experimentation, which is essentially create a model, test it, fail fast, learn from those failures, and then enhance and improve it further. And finally, value. Value is, of course, the marker of success. You, that is how you know whether you achieved the outcome of the digital transformation program. So, now let's look at how, in the case of Apollo, the CCDIV framework can be applied. Think about it from a customer standpoint. The customers, in this case the patients, are a dynamic network. So, one of the concepts that Apollo tried to think through in the transformation program is how they rethink the marketing funnel and how they create much more of an omnichannel experience. So, some of the examples of Apollo's initiatives that you would have seen is the Ask Apollo or the Apollo 24/7, the registration kiosks that they placed at the receptions of the hospitals. So, that's how one way by which they are trying to harness customer networks. How did they tap into competition by building platforms and not just products?

So, if you look at some of the initiatives like Dial30 or Portzo or MedMantra, these were examples of platform business models in which they were digitally disintermediating some of the other players who are in the value chain of service to the patient. Turning data into assets, in this case, data-driven decision-making like, for example, the Apollo Standards of Clinical Care or the consultant DSS. These are ways by which Apollo tried to leverage on the data that is available to them and convert them into assets. Innovation through rapid experimentation. You would have noticed Apollo talks about 72-hour feedback. They talk about post OP feedback. These are various different ways by which they try to get quick feedback to some of the experiments that they were doing to be able to create what they would call minimum viable products. And finally, the value proposition, or the value per se. For this, some of the concepts that Apollo tried to implement was how do they create parts out of a declining market for them? So, I would urge you all to consider looking at the CCDIV framework, not just from the perspective of some of the initiatives that Apollo put in place, but also if you look at the entire patient journey. So, the patient journey, as you know, starts with the OPD

consultation and goes all the way through admission, inpatient treatment, then the discharge process, and then the post-operative follow up. So, at every stage of this journey, you can see that Apollo was trying to put in place specific initiatives that would either reduce cost, or enhance the brand value, or improve the patient experience, and finally to improve the physician experience. So, I'll take a couple of examples to illustrate this. In the OPD part of the value chain, you would have noticed that they talk about initiatives like the Oscar Polo, the Apollo 24/7. The idea of these initiatives were to find ways by which they could differentiate themselves and enhance their brand. At the same time, they were also trying to improve the consultant experience. So, the consultant DSS was an initiative that was put in place, leading to better interactions for the physician with the hospital. Take the discharge process, which is another moment of truth for patients and for their caregivers.

The discharge summary being produced faster and in allowing for a quicker check-out then competition was certainly one way which they improved the customer experience, the patient experience, but also enhance their own brand. So, I suppose I made the point to you that the CCDIV framework can be a very useful one to understand a digital transformation. And the most important thing is for you to appreciate whether this is just a set of initiatives or whether they can actually be strung together in the form of a cohesive digital transformation journey. If they have been strung together in a cohesive journey, you will notice that they would have addressed the aspects of cost and cost competitiveness. They'd have addressed the aspects of improving their brand, of improving patient experience, of improving the physician experience. But importantly, you would have noticed that they will do this by addressing all the five elements of the CCDIV framework, which is their customers, the competition, the data, the innovation, and the value.

Video 4: Implementation Framework – Organisation

Now that we understand the why of aligning AI with strategy, let's explore the how. How you implement AI within your organisation through different organisational structure forms?

There are essentially three ways of organising an analytics function or an AI function within an organisation. The first model is a highly centralised model where the analytics is managed and organised in a central body that provides the insights for all the other regions, the branches, the functions, etcetera. In this case, the business responsible for analysing results is the central corporate organisation. They also govern the reporting structures, the references, the data, the quality, so on and so forth. This usually works in a straightforward business structure where the products are fairly homogeneous, the reporting and the analytics capability is fairly mature, and that the data that is used is predominantly used to meet SLAs. Think about, for example, a business process services company, they typically would adopt a centralised model. On the other hand of the spectrum, that is a distributed model. A distributed model is one in which there is autonomous analytic departments that report and are managed by every region by every branch or every function at the local level.

In this case, business reporting and analytic teams are distributed. They keep the business analysts very close to the business, as it should be, and there are multiple processes, there are multiple databases, there are multiple apps, so on and so forth. Now, you might think that this is very complex and inefficient, but it's perhaps necessary

when you have a complex business structure, often a structure that has grown through M&A's or through a varied product portfolio. In such a case, you do need mature reporting and analytic capabilities, but you're also probably using data as a tool to build the business. More often than not, you have what is called a hybrid model or a centre of excellence modeling. The hybrid model has processes that are owned centrally and yet other processes that are owned locally with support given in a way by the centre to the local units. In this case, usually businesses are responsible for performance measurement, for reporting and so on, and the COE provides the governance, the recruiting, the career management and so on and so forth. Most often this kind of a structure is deployed when you don't have a very complex business structure, but the reporting and analytic capabilities are mature and you are definitely thinking about data as a competitive advantage.

So, let's talk a little bit about these hybrid models or what we earlier referenced as the centre of excellence model. What are the different forms in which these hybrid models exist? One of them is what is called a community or practice model, where independent teams at every unit collaborate to share knowledge and skills. There is also something called the Hub and Spoke model. The Hub and Spoke model is an interesting one because you find similar work being done both at the headquarter as well as of the units, but the scope and the intent may be different. So, let's talk about a particular example where I was actually involved in setting up that analytics operating model. What they essentially did was created an analytics Hub at the headquarters and the role of the Hub was to develop the strategy, the governance to lead in the sense-making. They are the ones that house the data scientist to be able to build the data models. They provided analytics as a service to the units for ad hoc of a special projects that are more complicated than others. Every business unit, on the other hand, had their own analytics capability, but however, the analytics capability was not as sophisticated as the one that existed at the headquarters.

This was more in order to be able to interpret the data to be able to generate new insights and to be able to action on those insights. Now, usually what happens is sometimes at the Hub, there is another further Hub and Spoke arrangement. This is especially true for very, very complex organisation structures. The concept of Hub and Spoke further you can see three variations of it. In the first variation you have a very thick hub and very thin spokes. The second, both the hubs and spokes are fairly balanced and in the third, the spokes are thick, and the Hub is very thick. Now it depends on what you put in each of the hubs and the spokes. But by and large, the hub will have all the capabilities around data science, around governance, around reporting and around the aspects of career management. Whereas, the spokes will have the capabilities around basic reporting, around intermediate analytics, and therefore more around inside generation and inside interpretation. This space is evolving very rapidly with the introduction of the global capability centres or the shared services. It has evolved even further where many organisations are now maintaining a part of their analytics capability in their shared service organisations, a part on-shore with the business and that part is distributed further between the headquarters at the centre and the business units. It's a rapidly evolving space.

What I think, the bottom line that all of you as learners should appreciate is that there are multiple ways of organising your analytics capability. However, it is quite important to understand the trade-offs that you're making. The more centralised you are, obviously, you get greater economies of scale, but you're further away from the

business. And so, the likelihood of being able to develop models that are relevant timely is much lower, which is why people normally prefer a balanced Hub and Spoke model where the difficult activities are done at the center and more of the interpretation as well as the application bar is done in the spokes.

Video 5: Developing and Managing an AI-Skilled Workforce

Hi. In this section, we're going to talk about developing and managing an AI skilled workforce. As you know, AI as it continues to transform industries, data is quickly becoming the fuel that drives innovation. But raw data by itself is not enough. To leverage its power organisations require a workforce that is equipped with data and AI literacy. But what does data and AI literacy mean? I'd like us to think about all the data and AI competencies in three broad buckets. One is of course the bucket of the technical expertise that is needed to build models, to run models to interpret the data and the findings that come out of these models. So, they could include things like proficiency in AI algorithms, including machine learning, deep learning, and NLP, which is natural language processing. It could mean mastery of programming languages such as Python, Java and so on. Familiarity with AI frameworks like TensorFlow and PyTorch. Advanced knowledge of data processing, analysis, visualisation, expertise in deploying AI models in production environments, extracting, cleaning and analysing data to build AI models and expertise in specific languages. So, this is one set which is a technical expertise. The second type of expertise that people need is the domain or the subject matter expertise, which is essentially to understand what is the business problem and the business outcomes that the organisation is trying to solve for. And understanding the capabilities of AI as well as its limitations so that you can align these AI projects with the business goals. We spoke about it earlier in this module about the importance of aligning AI strategy to business strategy. That's best happens when you have a subject matter expert as a part of the team that is building the AI models. The other aspect of the domain expertise that is important is the ability to test and iterate. So, that happens usually after the model has been built, but when you iterate with production data as well as test data that's when the domain expertise becomes relevant as well. And then the third type of capability or competency that is needed is the consulting expertise. And I call this consulting expertise loosely because I'm trying to identify the skill required in terms of collaboration between the data scientists, the engineers, the domain experts and the business stakeholders so that you align the AI initiatives with the strategic initiative. This also incalls encouraging a data-driven culture across departments, fostering a foundation for AI adoption, communication, teamwork and essentially integration of AI capabilities with the existing business processes and workflows. So, as an example, if you were to create a people analytics team, I would suggest to you that you need three types of capabilities. One which is the analytics capability or the technical expertise that is needed. And typically this comes in the form of people who have deep expertise in data science or HR analytics. You then need HR functional experts who are experts in specific areas of HR such as employee engagement, employee experience, leadership, culture, what have you. And then finally, consulting acumen, which is the ability to appreciate the business implications of the people analytics to be able to bring the various cross-functional teams together and to be able to essentially manage the project to completion. This is a typical combination of skills that are needed in any AI/analytics team that you are trying to construct. But what are some of the roles? So, I would say to you that the key roles are that of the chief AI officer, the data scientists or the engineers who are the people who clean, analyse, interpret data to train AI models. They build and maintain the necessary data

infrastructure. And you have the domain experts with deep knowledge of the specific business problem. They are the ones who guide the data selection, the model development, and then they interpret the results. You have the project managers who keep the project on track. You have change management specialists who develop and implement the strategies to ensure employee buy in, and the business analysts who essentially are the ones who translate the business goals into actionable plans for the AI team. Now, how would you build this literacy? And then we come to the classic definitions of build, buy, borrow or bought. What does build mean?

Build essentially means that you train existing staff employees. You implement training programs which are tailored to different levels of data and AI expertise within your organisation. You offer introductory courses on data analysis and visualisation for all employees and then perhaps more in-depth programs on AI concepts and applications for specific roles. You can also see this in the form of upskilling and reskilling programs where you look at investing in program that can help your workforce adapt to the changing landscape. This is build. You also have the option to buy, which is essentially to go out and hire specific skills usually in the area or specialist areas of data science into the team. The borrow option is less used but should not be disregarded, especially in the hard to find skill areas. Borrowing includes taking people in contract, employing gig workers and things like that, or even crowdsourcing for that matter. And then finally, there is the bought aspect, which is all about what are the parts of the program or the AI modeling development that can be automated with the increased use of Gen AI in teams, much of the model building can now be automated significantly, not entirely, but quite significantly by using the new generation AI tools. So, again, the implementation part to building data and AI literacy in an organisation can be around the ideas of training, hiring, contracting slash using gig workers and then finally automating. Let's look at a couple of use cases, right? The first one I'd like to talk to you about is a global technology company. Essentially what they did was used an intelligent demand supply mapping algorithm to do a mapping of employees to the roles that exist. This was a technology solution that they found to be able to figure out where the gaps, skill gaps were and then deployed specific training programs to bridge that gap. Yet another example, is that of a global consulting firm who used personalised learning by, through a concept called learning boards and used it to significantly improve the AI literacy across the organisation. And some of the outcomes that they saw was in the form of enhanced productivity, much, much better employee engagement and finally increased operational efficiency. So, there are many examples of their organisations have successfully, shall I say reskilled their organisation to make the whole organisations data literacy or data quotient much higher. And today with the use of technology based learning solutions like Pluralsight and the latest that you probably are aware of is Accenture has launched a new business called Learn Vantage. And this whole thing is essentially an opportunity by which individuals, whether it's in corporate or outside, can go and get competency assessment done, get a personalised curriculum, and based on the personalised curriculum, can source courses from a variety of different third party sources such as Pluralsight, such as Unacademy and various other sources. I also wanted to give you another example, and this is a pretty iconic example from an equally iconic company, Google. What did Google do? What does it continue to do to train its own employees? First of all, the courses are designed in such a way that it's accessible to people with a wide range of backgrounds ensuring that even those who don't have a technical background can grasp the basics of machine learning. And it includes interactive coding exercises, they use TensorFlow, which allows participants to get hands on experience with real world data and machine learning models. They have a very

comprehensive curriculum that covers essential topics like supervised learning, neural networks, model training and evaluation and so on. Besides these public courses, Google also offers internal training programs which are tailored to different roles within the company. So, they have gone down the path of doing role based training to provide a wide variety of tools like Datacom, Tableau, Microsoft Power BI, IBM's Data Science Experience and also provide access to Khan Academy and then most of the employees that have free courses on our idea of various different subjects. So, if you think we are, what is the path of the process that Google follows? It effectively starts by assessing the skill gap. So, it looks at its current skill landscape does a little bit of a learning assessment and identifies which are the areas where the maximum knowledge gaps exist. It then creates customised learning pathways which are structured learning pathways that include foundational courses and more advanced courses. Quite importantly, they have to continuously work to create a culture of learning. So, they encourage people to spend time on learning by providing access to resources was more importantly making sure that they are rewarded for improving their competencies. Using real world projects is very important because it makes the learning very practical. And secondly, it gives the learners a chance to interact with the data and makes it far more experiential. And then finally, I think learning doesn't happen on yourself. Google recognises that learning is also a function of networking and working with others through community learning and therefore they leverage internal expertise to mentor and then to train employees and overall to foster a collaborative learning environment. Thank you.

Video 6: Leadership and AI Advocacy

Hello. In this segment, we'll talk about leadership and AI advocacy. As you know, we've been talking about implementing AI in organisations, and so far we have covered the ideas of how you align your AI strategy to the business strategy. We also talked about organisation and the type of organisation structure forms that you need to be able to implement AI at scale. We then went on to talk about what it does AI and data literacy actually mean and how do you improve the data quotient and the AI quotient within organisations. I now want to talk to you about leadership and why is that? Because we believe that leaders play a pivotal role in shaping an organisation's future. In the age of AI, this responsibility extends to not only championing adoption of AI but also fostering an AI-ready workforce and ensuring responsible development and deployment. Leader service champions who can articulate the benefits of AI and foster an environment that is conducive to change and to innovation. Today, I think we will all agree that AI is no longer in the experimental mode. In fact, it is now moving into the exponential mode. We are at, as they say, a discontinuity point where, due to the combinatorial effects of many technologies coming together, AI has almost become a part of everyday life, both at home as well as at work. Having said that, the AI is not a risk-free pursuit. In fact, there is growing realisation of the need of ethical and responsible use. Let me take a couple of examples to make the point. Look at it from the point of the planet. While on the one hand, AI is helping us make climate predictions, it is helping us to improve our decision-making for decarbonisation and carbon transition. On the other hand, I think we are all of it, that we are adding significantly to the warming of the planet because of the data centres and because of the amount of energy that they consume.

Look at it from the point of view of organisation. AI is a source of innovation, it is a source of business value. But on this at the same time, if you ask many business leaders, they bemoan the fact that they haven't been able to scale AI. They haven't been able to get past the graveyard of POCs and pilots. Governments are concerned about the unintended consequences of AI. They are putting in place regulations.

They're also worried about the obsolescence risks that are being caused by AI. And finally, from an every person's perspective, from a citizen's perspective, we are users of AI, but not all of us really understand what it is and what it can help us deliver. And more importantly, I don't think all of us understand what it means for the data that the AI algorithms are consuming and how much of that is being sourced from each one of us, and what it means for our privacy. In the context of all of this, it becomes therefore extremely important to think about who is a responsible leader who will be able to address some of these issues. But before we do that, let's try and ask ourselves what are some of the big, sort of dimensions and decision points that leaders are trying to deal with.

One, they're trying to determine who is responsible for AI implementation within an organisation. Now you notice that is a growing trend of AI risk officers, or sort of either on a standalone basis or combined with the CTO or the general counsel. Leaders are also concerned about creating a culture where AI is used in a responsible way. You've heard a lot of stories about how data was used without the permission of the users in a way that actually was quite harmful to them. So, therefore, the need to build a culture within organisations where data is used responsibly. Talent, leaders are also concerned about the availability of tech talent and whether they should buy talent or build it internally to be able to keep pace. So, these are some of the decision points, or the dimensions, as I say, that leaders are trying to deal with. But specifically, what are some of the dilemmas that AI poses to them? You might have all heard this concept about AI replacing jobs, but the jury is out. We are not very sure whether AI is replacing jobs or whether it is simply changing the nature of those jobs, whether it is augmenting jobs, and actually, are we then preparing for a new future where humans and machines will need to collaborate? What will teams look like in the future? Where will work be done from in the future? These are important issues that leaders and organisations need to deal with. Second, how do you reduce the systemic bias in organisation? I think leaders have a responsibility not in perpetuating those biases but in demystifying them and making sure that the human biases don't creep into the way data is collected and so, therefore, the predictions that are made by the algorithm. The third dimension of the dilemma that the leaders have to face is to what extent do they intrude on the privacy interests of the individuals versus to what extent do they improve the online experience of their customers. How might we ensure the online experience is enhanced but without their private lives being at risk to exposure and to manipulation?

Yet another dilemma is around crime. As you know, cybercrimes is on the rise. AI can be used both to solve for the cybercrimes to counter it. But on the other hand, AI requires so much of data, and that then makes us more and more vulnerable to cybercrimes. And finally, the social impact of AI. It is still early days. We have already seen how some social media platforms have been used during elections and before elections to create divided societies. On the other hand, AI also has the capability of creating much greater cohesion. So, how do we unite people to address these challenges as opposed to polarising them? So, AI poses several questions. Everything from replacement of jobs to managing of biases to assuring privacy of data to resolving crimes to actually the social impact. And it is only an extremely responsible and mature leader who has to be able to address these issues squarely and fairly. Thank you.
